Understanding CD4 Cells
and CD4 Cell Tests

Last updated: March 2, 2022

Together, we can change the course of the HIV epidemic…one woman at a time.

Understanding CD4 Cells and CD4 Cell Tests

**CD4 Cell (or “T Cell”):** A type of **white blood cell** that HIV infects and destroys, **weakening the immune system.**
The Basics

- White blood cells like CD4 cells are an important part of your immune system.
- Your immune system protects your body by fighting germs and infections.
- As the immune system loses CD4 cells, it becomes less able to fight off germs.
  - When people living with HIV lose a lot of CD4 cells, they are at risk of getting AIDS-related opportunistic infections (OIs) – which can cause serious illness or death.
The number of CD4 cells a person has (their **CD4 count**):

- Gives a picture of the health of your immune system
- Usually decreases as HIV disease gets worse
- Can help your health care provider tell whether your current treatment and plan of care is working for you

A normal CD4 count is about 500 to 1,500

Without HIV treatment, HIV infects and destroys more and more CD4 cells, and the CD4 count goes down

Lower CD4 count: more likely to develop OIs
CD4 Count and HIV

**CD4 count > 500:**
- People with CD4 counts above 500 cells
  - Usually have a fairly normal immune system
  - Are at low risk for OIs

**CD4 count < 200:**
- People with CD4 counts below 200 cells
  - Are diagnosed with AIDS
  - Are at risk for developing serious OIs
  - May need to take medications to prevent OIs
HIV treatment is recommended for everyone living with HIV, no matter their CD4 count

– Also strongly recommended for people in certain situations
– Should be offered to people at risk of transmitting HIV to their sexual partners

CD4 counts often increase when effective HIV treatment is started because the drugs slow or stop HIV from making copies of itself
CD4 Count and HIV Treatment

- CD4 counts can go down again if you are unable to take your HIV drugs correctly or if your HIV becomes resistant to the drugs.
- Along with your viral load, your CD4 count is an important tool for monitoring your HIV and how well your HIV drugs are working.
CD4 Cell Test

• Simple blood test ordered by your health care provider
• When you first start HIV care, get a "baseline" CD4 cell test
  – Gives a picture of your immune system when you first enter into care
• When starting care, CD4 count is usually checked every 3-6 months
  – More frequent CD4 cell tests may be needed if your count is low/falling, or if you are starting or changing treatment
  – If you’ve been on HIV drugs for more than 2 years, are virally suppressed, and have a CD4 count over 300, you may only need to have your CD4 count checked once a year

CD4 Cell Test

• Many factors can affect your CD4 count, including
  – Time of day
  – Level of stress
  – Your menstrual cycle
  – Infections such as the flu

• If CD4 cell test result is surprising, your provider will probably order a second test

• Don’t worry too much about a single test result
  – Trends over time are more important
CD4 Percentage

- Tells what percent of total white blood cells are CD4 cells
  - Normal CD4 cell percentage is about 30 to 60 percent
  - Your health care provider will want to check this number in addition to your CD4 count
- CD4 percentage may be more reliable measurement than CD4 count
  - Tends to change less between measurements
- Treatment guidelines are based on CD4 counts, not CD4 percentages

www.thewellproject.org
The Bottom Line

• If you begin treatment when CD4 count and percentage are low (<200), it may take longer for CD4 numbers to increase
• If viral load is undetectable, HIV is not growing or spreading
• May take time and patience to see CD4 counts increase
• Keeping track of trends in CD4 count can help you and your provider make decisions about starting/changing treatment

Regular visits with your healthcare provider and regular CD4 cell, viral load and other tests are an important part of taking charge of your health!
